Abstract

We probe the existence of supersymmetric vacua of the type IIB orientifold of the elliptic Calabi-Yau space $\mathbf{P}_{11169}[18]$ where generically two complex structure moduli z_i , the dilaton τ and the two Kähler moduli T_i are stabilized by fluxes and gaugino condensates. The usual KKLT procedure, which integrates out the complex structure moduli *and the dilaton*, actually has to be modified, such that one keeps the dependence on τ . We derive explicitly the resulting effective superpotential $W_{eff}(\tau)$ for the dilaton for various flux combinations. As this is actually a non-holomorphic quantity one must properly work with the G -function. The remaining SUSY equations for τ and the T_i can be resolved explicitly.

1 Introduction

The issue of moduli stabilization in superstring theory gained new interest when it was observed [1], [2] that by adding 3-form fluxes, inducing a superpotential W_{flux} , in the type IIB theory on a Calabi-Yau X the complex structure moduli z_i and the dilaton τ can be frozen. In a corresponding orientifold model, reducing $4D$ space-time supersymmetry to $N = 1$, the presence of orientifold planes leads to cancellation of D -brane charges against the effects of $D3/D7$ -branes and 3-form fluxes in the tadpole cancellation condition.

KKLT [3] combined this with a non-perturbative superpotential W_{np} describing gaugino condensation [4] (or Euclidean $D3$ -instantons [5]) such that the remaining Kähler moduli T_i could be stabilized also. Here, for warped $D7$ -branes, the non-abelian gauge theory on a stack of $D7$ -branes must allow for a non-vanishing gaugino condensate; for Euclidean $D3$ -brane instantons the number of fermionic zero-modes on the world-volume is relevant (here the fluxes have a subtle impact on the relevant count [6]).

More precisely, the scenario of KKLT amounts (working at supergravity level at large τ and T_i) to a two-step procedure where z_i and τ have been fixed by fluxes first, leading just to a constant effective superpotential contribution W_0 , and in a second step, in the resulting effective theory, the Kähler moduli T_i are stabilized (this decoupling procedure assumes that the z_i and τ are much heavier than the T_i so that they can be integrated out first). The resulting supersymmetric AdS -vacuum was then uplifted to a non-supersymmetric dS -vacuum by adding anti $D3$ -branes (for whose stability the (mass)² eigenvalues of the fixed scalars should be already positive in the AdS -vacuum and not just negative and fulfilling the Breitenlohner-Freedman bound).

In [7] stability conditions were derived (for a susy AdS -vacuum with stabilized moduli) in a more general case than the decoupling limit of KKLT. There only the z_i (if heavy enough) were integrated out, leading to an effective superpotential contribution $W_{eff}(\tau)$

$$W_{flux}(z_i, \tau) = A(z_i) + \tau B(z_i) \xrightarrow{D_i W_{flux}=0} W_{eff}(\tau) \quad (1.1)$$

(define for later $\gamma := \tau_2 W''_{eff}/W'_{eff}$). There as ansatz for the Kähler potential is used

$$K^{(T)}(T) + K(\tau) = -3 \log(T + \bar{T}) - \log(\tau - \bar{\tau}) \quad (1.2)$$

The supersymmetric stationary points fulfill $D_i W = 0$. Their nature is determined by the second derivatives V'' of the scalar potential of the combined superpotential $W = W_{eff}(\tau) + C e^{-aT}$ (here in principle the C was also z_i -dependent, but is set constant for now): this matrix splits into 'real' and 'imaginary' (axionic) parts V''_{0M} and V''_{0A} and the stability condition for V from the matrix determinants (at large T) is $|\gamma| > 1$.

In [8] it was pointed out that this program should be properly enhanced to take into account two points. First, the Kähler potential $K(z_i)$ of the complex structure moduli, more precisely the effective version $K_{eff}(\tau) = K(z_i(\tau))$ of it arising after integrating out the z_i , has to be added to $K(\tau) = -\ln(\tau - \bar{\tau})$. Secondly, as the conditions $D_i W_{flux} = 0$ for integrating out the z_i are (because of the covariant derivative involving the Kähler potential) actually non-holomorphic, it turns out that the effective superpotential $W_{eff}(\tau)$ arising from $W_{flux}(\tau, z_i)$ is also actually a non-holomorphic quantity. Therefore one should compute the scalar potential in the form $V = e^G (G^{i\bar{j}} G_i G_{\bar{j}} - 3)$ where

$$G = K(\tau) + K_{eff}(\tau) + K(T) + \ln |W_{eff} + W^{(T)}|^2 \quad (1.3)$$

and the z_i should be integrated out by $G_i = 0$ or equivalently (for $W \neq 0$) $D_i(W_{flux} + W^{(T)}) = 0$, leading actually to $z_i(\tau, T)$ instead of just $z_i(\tau)$. This is described in sect. 5.

Just as in the case of KKLT this program now should be carried out for concrete examples. We have chosen the elliptic Calabi-Yau $X = \mathbf{P}_{11169}(18)$ and its corresponding orientifold model for which the KKLT program was carried through [9], cf. also [10], [11], [12]. For some examples of choices of fluxes we derive here W_{eff} and K_{eff} in completely explicit form. For one fully worked out case we find that no supersymmetric solutions exist. For the procedures cf. sect. 6. Here we were just searching for SUSY solutions; more generally one would search for non-SUSY stationary points of the resulting V .

In one concrete example we take the flux combination (where we specialise to $c = 3d$)

$$(e_R^a | m_R^a) = (0, g, 0 | 0, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | 0, c, d) \quad (1.4)$$

which gives for $W_{flux} = gF_1 + az_1 + bz_2 + \tau(cz_1 + dz_2)$ the explicit expression

$$W_{flux}(z_i, \tau) = g \left(-\frac{1}{2}(3z_1 + z_2)^2 + \frac{3}{2}(3z_1 + z_2) + \frac{17}{4} \right) + (a + \tau c)z_1 + (b + \tau d)z_2 \quad (1.5)$$

The Kähler potential of the complex structure moduli z_i is given by (where $y_k = \text{Im} z_k$)

$$K(z_1, z_2) = -\ln \left[y_1 (3y_1^2 + 3y_1 y_2 + y_2^2) + i\xi \right] \quad (1.6)$$

The fourfold we work on following [9] has a base B_3 , itself $\mathbf{P}_Z^1$ fibered over $B_2 = \mathbf{P}^2$; the latter is embedded as divisor r and r_∞ in B_3 at $z = 0$ and $z = \infty$, respectively, and has a G_2 singularity along r and an E_6 or E_8 singularity along r_∞ . With the volumes $\tau_1 := \tau_r = \frac{1}{2}t_1^2$ and $\tau_2 := \tau_{r_\infty} = \frac{1}{2}(t_1 + 6t_2)^2$ of the divisors r and r_∞ a superpotential

$$W^{(T)} = C_1 e^{-2\pi a_1 \mathcal{T}_1} + C_2 e^{-2\pi a_2 \mathcal{T}_2} \quad (1.7)$$

is generated (with the complexified 4-cycle-volumes $\mathcal{T}_j = \tau_j + i\theta_j$ where $\theta_i = -\int_{r(\infty)} C_4$). For the Kähler form $J = t_1 L + t_2 r_\infty$ (cf. below) one has the Kähler potential (so $\tau_2 > \tau_1$)

$$K(t_i) = -2 \ln(\tau_2^{3/2} - \tau_1^{3/2}) \quad (1.8)$$

In *section 2* we consider the $N = 2$ theory from which the orientifold model is derived. We give the prepotential, the Kähler potential and the period vector for the complex structure moduli, leading to a concrete expression of W_{flux} . In *section 3* we give the $N = 1$ orientifold theory with its Kähler potential. In *section 4* we recall the KKLT procedure for the model. In *section 5* we show how one works for W_{eff} non-holomorphic actually with the G function. In *section 6* we derive $W_{eff}(\tau, \mathcal{T}_k)$ for various flux combinations and give a complete analytical treatment of the remaining SUSY conditions for τ and the $\mathcal{T}_k$.

2 The $N = 2$ parent theory on the Calabi-Yau X_3

We consider the elliptic Weierstrass fibration $\pi : X \rightarrow B_2$ over $B_2 = \mathbf{P}^2$. Some data of such elliptic Calabi-Yau threefolds (with section σ) over B_2 are (by adjunction) [15]

$$\sigma^2 = -c_1\sigma \quad (2.1)$$

$$c_2(Z) = 12c_1\sigma + c_2 + 11c_1^2 \quad (2.2)$$

One has $h^{1,1}(X) = 2$ from the divisors σ (the embedded base of the fibration) and $L := \pi^{-1}l$ where l is the line in B_2 . Furthermore $c_3(X) = -60c_1^2$ gives $h^{2,1}(X) = 272$.

Classical intersection numbers on Z

With $H := \sigma + 3L$ and L as divisors one finds using (2.1)

$$H^3 = 9, \quad H^2L = 3, \quad HL^2 = 1, \quad L^3 = 0 \quad (2.3)$$

Furthermore one gets from (2.2) that that

$$c_2(Z) \cdot L = 36, \quad c_2(Z) \cdot H = 108 + (-12c_1^2 + c_2 + 11c_1^2) = 102 \quad (2.4)$$

Kähler potential

Let us give the corresponding Kähler potential for the Kähler form $\tilde{\mathcal{J}} := t_1H + \tilde{t}_2L$

$$e^{-K} = V = \frac{1}{6} \left(9t_1^3 + 9t_1^2\tilde{t}_2 + 3t_1\tilde{t}_2^2 \right) \quad (2.5)$$

Remark: This is the Kähler potential in the basis adapted to the prepotential given below. Later, when we consider the orientifold $N = 1$ theory derived from the $N = 2$ Calabi-Yau theory, the relevant divisors to consider will be suitable quotients related to σ (then called r) and L . For this reason let us also give here already the Kähler potential for the Kähler form $\mathcal{J}' := t_1\sigma + t_2'L$, i.e. with intersection numbers

$$\sigma^3 = 9, \quad \sigma^2L = -3, \quad \sigma L^2 = 1, \quad L^3 = 0 \quad (2.6)$$

$$e^{-K} = V = \frac{1}{6} \left(9t_1^3 - 9t_1^2t_2' + 3t_1(t_2')^2 \right) \quad (2.7)$$

The prepotential and the periods

Expressing the middle homology and cohomology in terms of a symplectic basis, i.e. a basis of 3-cycles A^a and B_b with $A^a \cap B_b = -B_b \cap A^a = \delta_b^a$ and $A^a \cap A^b = B_a \cap B_b = 0$ and a basis of 3-forms α_a and β^b (where $a, b = 0, 1, \dots, h^{2,1}$; let $n = h^{2,1} + 1$)

$$\int_{A^b} \alpha_a = - \int_{B_a} \beta^b = \delta_a^b, \quad \int_X \alpha_a \wedge \beta^b = - \int_X \beta^b \wedge \alpha_a = \delta_a^b \quad (2.8)$$

Such a symplectic basis is only defined up to $Sp(2n, \mathbf{Z})$ transformations, as these preserve the symplectic intersection form. The periods are defined via the holomorphic 3-form Ω

$$\int_{A_a} \Omega = X^a, \quad \int_{B^b} \Omega = \mathcal{F}_a \quad (2.9)$$

The periods are collected in the period vector, $\Pi = (X^0, \dots, X^n, F_0, \dots, F_n)$. This is a function of the complex structure moduli $z^i = X^i/X_0$ ($i = 1, \dots, h^{2,1}$) and inherits the holomorphic freedom of Ω and is defined up to holomorphic rescalings $\Omega \rightarrow f(z_i)\Omega$.

Here the prepotential $\mathcal{F}$ is given by (with $\xi' = \frac{\zeta(3)}{2(2\pi i)^3} \chi(X) \approx -1.3i$ and $q_i = e^{2\pi i z_i}$)

$$\begin{aligned} \mathcal{F} &= -\frac{C_{ijk}}{3!} \frac{X^i X^j X^k}{X^0} + \frac{A_{ij}}{2} X^i X^j + c_i X^i X^0 - \xi' (X^0)^2 + f(q) (X^0)^2 \\ &= (X^0)^2 \mathcal{F} = (X^0)^2 \left(-\frac{C_{ijk}}{3!} z^i z^j z^k + \frac{1}{2} A_{ij} z^i z^j + c_i z^i - \xi' + f(q) \right) \end{aligned} \quad (2.10)$$

where $C_{ijk} = \int J_i \wedge J_j \wedge J_k = D_i \cap D_j \cap D_k$ are the classical intersection numbers and $c_i = \frac{1}{24} \int c_2(X) J_i$ (the quadratic coefficients A_{ij} are unphysical and not completely fixed).

In our case this becomes (we take later $A_{11} = 9/2, A_{12} = 3/2, A_{22} = 0$ with [16], [9])

$$\mathcal{F} = -\frac{1}{6} (9z_1^3 + 9z_1^2 z_2 + 3z_1 z_2^2) + \frac{9}{4} z_1^2 + \frac{3}{2} z_1 z_2 + \frac{17}{4} z_1 + \frac{3}{2} z_2 - \xi' \quad (2.11)$$

With this prepotential the period vector becomes (where $F_a = \partial F / \partial X^a$ and $\mathcal{F}_i = \partial \mathcal{F} / \partial z^i$ for the prepotential $F(X^a)$ in homogeneous coordinates ($a = 0, 1, \dots, h^{2,1}$) and $\mathcal{F}(z^i)$ in inhomogeneous coordinates $z^i = X^i/X^0$ ($i = 1, \dots, h^{2,1}$), respectively)

$$\Pi = \begin{pmatrix} X^0 \\ X^i \\ F_0 \\ F_i \end{pmatrix} = X^0 \begin{pmatrix} 1 \\ z^i \\ 2\mathcal{F} - z^i \mathcal{F}_i \\ \mathcal{F}_i \end{pmatrix} = X^0 \begin{pmatrix} 1 \\ z^i \\ \frac{C_{ijk}}{3!} z^i z^j z^k + c_i z^i - 2\xi' + \dots \\ -\frac{C_{ijk}}{2} z^j z^k + A_{ij} z^k + c_i + \dots \end{pmatrix} \quad (2.12)$$

The Kähler potential for the complex structure moduli space is given by

$$\begin{aligned} K(z_i) &= -\ln \left(i \int \Omega \wedge \bar{\Omega} \right) = -\ln (-i \Pi^\dagger \cdot \Sigma \cdot \Pi) \\ &= -\ln \left(i |X^0|^2 ((z_i - \bar{z}_i)(\mathcal{F}_i + \bar{\mathcal{F}}_i) - 2(\mathcal{F} - \bar{\mathcal{F}})) \right) \end{aligned} \quad (2.13)$$

with $\Sigma = \begin{pmatrix} 0 & 1_n \\ -1_n & 0 \end{pmatrix}$. Further one has in the dilaton sector $K(\tau) = -\ln(-i(\tau - \bar{\tau}))$.

One calculates explicitly (with $z_k = x_k + iy_k$; $\xi := -\xi'$)

$$K(z_1, z_2) = -\ln \left(y_1 (3y_1^2 + 3y_1y_2 + y_2^2) + i\xi \right) \quad (2.14)$$

(up to an additive constant). Compare the Kähler potential (2.14) for the complex structure moduli (expressed in the y_k) with the Kähler potential (2.5) for the Kähler moduli (expressed in $t_1 = \text{Re } T_1$, $\tilde{t}_2 = \text{Re } T_2$ and with respect to H and L)

$$K(t_1, \tilde{t}_2) = -\ln \left(\frac{1}{2} (3t_1^3 + 3t_1^2\tilde{t}_2 + t_1\tilde{t}_2^2) \right) \quad (2.15)$$

Restricting the consideration of the complex structure moduli to two of them (as recalled below) one gets the same Kähler potential as for the Kähler moduli by mirror symmetry.

Note that Z has the (weighted) projective embedding as hypersurface $\mathbf{P}_{11169}$ [18]

$$x_1^{18} + x_2^{18} + x_3^{18} + x_4^3 + x_5^2 - 18\psi x_1x_2x_3x_4x_5 - 3\phi x_1^6x_2^6x_3^6 = 0 \quad (2.16)$$

Here actually only 2 of the full set of 272 deformations are displayed. The group $\Gamma = \mathbf{Z}_6 \times \mathbf{Z}_{18}$ is a symmetry of the moduli space and fixes the two-parameter subspace in (2.16). One is lead to this specific Calabi-Yau by the mirror construction and the periods of Γ -invariant cycles are its six periods. One proceeds to find flux-vacua by working in the Γ -invariant part of the moduli space (turning on only invariant fluxes); i.e. one turns on fluxes just on these cycles and has $D_i W = 0$ in non-invariant directions as the resulting superpotential and Kählerpotential are invariant. Effectively it is thus consistent to set all other moduli to zero and work only on the moduli in (2.16) and their associated fluxes.

2.1 The flux superpotential

In terms of the periods, the flux-superpotential is¹

$$\begin{aligned} W_G &= \int_X G_3 \wedge \Omega = (2\pi)^2 \alpha' \left((e_R^a - \tau e_{NS}^a) \cdot \Pi_{3+a} - (m_R^a - \tau m_{NS}^a) \cdot \Pi_a \right) \\ &= (2\pi)^2 \alpha' \left(\sum_{a=0}^k (e_R^a - \tau e_{NS}^a) F_a - (m_R^a - \tau m_{NS}^a) z_a \right) \end{aligned} \quad (2.17)$$

where the integral vectors of fluxes along the cycles occur as precoefficients. More precisely the fluxes H_R and H_{NS} are elements of $H^3(Z, \mathbf{Z})$ quantised as follows

$$e_{R/NS}^a = \frac{1}{(2\pi)^2 \alpha'} \int_{A^a} H_{R/NS} \in \mathbf{Z}, \quad (m_{R/NS})_a = \frac{1}{(2\pi)^2 \alpha'} \int_{B_a} H_{R/NS} \in \mathbf{Z} \quad (2.18)$$

This amounts to a $D3$ -charge carried by the fluxes

$$N_{flux} = L = \frac{1}{2} (e_R^a, m_R^a) \cdot \Sigma \cdot (e_{NS}^a, m_{NS}^a)^t = \frac{1}{2} \sum_{a=0}^k e_R^a m_{NS}^a - m_R^a e_{NS}^a \quad (2.19)$$

¹note that for two three-forms one has $\int \phi \wedge \chi = \sum_a \int_{A^a} \phi \int_{B_a} \chi - \int_{B_a} \phi \int_{A^a} \chi$

3 The $N = 1$ theory and the orientifold limit of the fourfold

Let $\pi : X_4 \rightarrow B_3$ denote the projection of the elliptic fibration of a Calabi-Yau fourfold in F -theory. We consider the case that B_3 is $\mathbf{P}^1$ -fibered over the base B_2 . In the orientifold limit a $D4$ singularity is realized.

In the type IIB string theory one describes B_3 as quotient by a holomorphic involution of a Calabi-Yau threefold Z , branched at the B_3 -location of the singularities of the elliptic fibration of X_4 (D_4 singularities corresponding to an $O7$ -plane and four coincident $D7$ -branes). D -branes are introduced to cancel the RR tadpoles produced by the orientifold plane. If Z is given as a hypersurface in an ambient $\mathbf{P}^4$ this involution might be given by $z_1 \rightarrow -z_1$.

The dilaton is the complex structure modulus of the elliptic F -theory fibre.

$$\begin{array}{ccc} Z & \longrightarrow & B_3 \\ \downarrow E & & \downarrow \mathbf{P}^1 \\ B_2 & = & B_2 \end{array} \quad (3.1)$$

B_3 inherits the Kähler and complex structure moduli which are even and odd, respectively, under the involution.

Classical intersection numbers on B_3

The $\mathbf{P}^1$ -fibration of B_3 over B_2 can be described as projectivization $\mathbf{P}(Y)$ of a vector bundle $Y = \mathcal{O} \oplus \mathcal{T}$ with $\mathcal{T}$ a line bundle over B_2 .

Let $\mathcal{O}(1)$ denote a line bundle on the total space which restricts on each $\mathbf{P}^1$ fibre to the corresponding line bundle over $\mathbf{P}^1$ and let $r = c_1(\mathcal{O}(1))$ and $t = c_1(\mathcal{T})$ so that the cohomology of B_3 is generated over B_2 by r with the relation $r(r+t) = 0$ (as the two sections are disjoint: one has $r = r_0$ the divisor given by B_2 itself inside B_3 , at the zero-section of the $\mathbf{P}^1$ -fibration; the section at infinity is given by $r_\infty = r+t$). Concretely take $B_2 = \mathbf{P}^2$ and $t = 6l$. Here we denote the line in B_2 by l and its preimage in B_3 by $L = \mathbf{F}_6$ (one has $Lr^2 = (r|_L)^2 = (l)_L^2 = -6$; furthermore $Lr_\infty^2 = 6$).

One has the following intersection numbers in B_3 (the first three relations are obvious)

$$L^3 = 0, \quad L^2r = L^2r_\infty = 1, \quad Lr_\infty^2 = 6, \quad r_\infty^3 = r^3 = 36 \quad (3.2)$$

For this note first that by adjunction

$$c(B_3)|_D = (1 + D)\left(1 + c_1(D) + c_2(D)\right)|_D \quad (3.3)$$

one has the relation

$$c_2(B_3) \cdot D = D^2 \cdot c_1(B_3) - D^3 + \int_D c_2(D) \quad (3.4)$$

Further one has for the $\mathbf{P}^1$ -fibration defined by t that (unspecified c_i refer always to B_2)

$$\begin{aligned} c_1(B_3) &= 2r + c_1 + t \\ c_2(B_3) &= 2c_1r + c_1t + c_2 \end{aligned} \quad (3.5)$$

again from adjunction $c(B_3) = (1 + c_1 + c_2)(1 + r)(1 + r + t)$. (3.4) now gives $r^3 = 36$ as

$$\begin{aligned} c_2(B_3) \cdot r &= (-c_1t + c_2)r = -c_1t + 3 \\ r^2 \cdot c_1(B_3) - r^3 + \int_r c_2(r) &= -r(c_1t + t^2) + r^3 + 3 = -c_1t - 36 + r^3 + 3 \end{aligned}$$

The Kähler potential

One can now compute the Kähler potential for the Kähler form $J' := t_1L + t_2r$. Alternatively and equivalently one can consider r_∞ instead of r

$$J = t_1L + t_2r_\infty \quad (3.6)$$

One gets for the divisor volumes $\tau_{r(\infty)} = r(\infty)J^2/2$ and for the total volume $V = J^3/6$

$$\begin{aligned} \tau_1 := \tau_r &= \frac{1}{2}t_1^2 \quad , \quad \tau_2 := \tau_{r_\infty} = \frac{1}{2}(t_1 + 6t_2)^2 \\ V &= \frac{1}{6}(3t_1^2t_2 + 18t_1t_2^2 + 36t_2^3) = \frac{1}{36}\left((t_1 + 6t_2)^3 - t_1^3\right) = \frac{\sqrt{2}}{18}(\tau_2^{3/2} - \tau_1^{3/2}) \end{aligned} \quad (3.7)$$

implying that $\tau_2 > \tau_1$ in the Kähler cone. With this one gets the Kähler potential

$$K(t_i) = -2 \ln V \quad (3.8)$$

Remark: For direct comparison with the Kähler potential (2.7) of the $N = 2$ parent theory let us also give here the Kähler potential w.r.t. J' (i.e. σ above becomes r below)

$$e^{-\frac{1}{2}K} = V = \frac{1}{12}\left(9(2t'_2)^3 - 9(2t'_2)^2t_1 + 3(2t'_2)t_1^2\right) \quad (3.9)$$

4 Integrating out z_i and τ and working with W_0

The stabilisation of τ and the z_i is achieved from the conditions

$$D_i W = \partial_i W + (\partial_i K) W = 0 \quad , \quad D_\tau W = \partial_\tau W + (\partial_\tau K) W = 0$$

In the given example one finds a stationary point for the values² [9] $z_1 = i = z_2, \tau = 3i$.

This vacuum of³ $W = 0$ is reached for the following flux combination of $N_{flux} = 352$

$$(e_R^a | m_R^a) = (20, 0, 0 | 0, -69, -28) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, -4, 0 | 49, 18, 6) \quad (4.1)$$

$$\begin{aligned} W &= 69z_1 + 28z_2 + 20F_0 - \tau \left(-49 - 18z_1 - 6z_2 - 4F_1 \right) \\ &= 30z_1^3 + 30z_1^2 z_2 + 10z_1 z_2^2 + 154z_1 + 58z_2 + 40\xi + \tau \left(-2(3z_1 + z_2)^2 + 27z_1 + 9z_2 + 66 \right) \end{aligned}$$

4.1 The Kähler stabilizing superpotential

[9] find no divisors leading to an instanton contribution in the superpotential following the necessary condition $\chi(D) = 1$ for the arithmetic genus [5].⁴ One computes $\chi(\pi^{-1}C) = -C^2 c_1(B_3)/2$ [13]. Recall now that the base B_3 of X_4 was $\mathbf{P}_z^1$ fibered over $B_2 = \mathbf{P}^2$ and one had divisors $C = r$ and r_∞ in B_3 as sections of this $\mathbf{P}_z^1$ fibration at $z = 0$ and $z = \infty$, respectively. For the projection $pr : B_3 \rightarrow B_2$ (with $t = nl$, say) one finds for the pr -horizontal divisors (in B_3) r and r_∞ and for the pr -vertical divisor $pr^{-1}P$ (for $P = al$)

$$\chi(\pi^{-1}r_{0/\infty}) = \frac{1}{2}t(\pm c_1 - t) = \frac{1}{2}n(\pm 3 - n) \quad , \quad \chi(\pi^{-1}pr^{-1}P) = -P^2 = -a^2 \quad (4.2)$$

So one has to rely solely on gauge type divisors (where contributions are induced from gaugino condensation; cf. also [14]). The concrete fourfold we work with following [9] has actually a G_2 (not D_4) singularity along r and an E_6 or E_8 singularity along r_∞ . This leads to values of $\chi(X_4)/24$ of 273, 129, respectively (note however that $N_{flux} = 352$).

With the volumes $\tau_1 := \tau_r$ and $\tau_2 := \tau_{r_\infty}$ of the divisors r and r_∞ a superpotential

$$W = W_0 + C_1 e^{-2\pi a_1 \mathcal{T}_1} + C_2 e^{-2\pi a_2 \mathcal{T}_2} \quad (4.3)$$

is generated where we introduced the complexified 4-cycle-volumes $\mathcal{T}_j = \tau_j + i\theta_j$ with $\theta_i = -\int_{r_{(\infty)}} C_4$. Assuming W_0 real (and $C_i = 1$) and that the two exponential terms should equal approximately W_0 at the critical point, they should be also approximately equal there. In view of $\tau_1 < \tau_2$ this means that $a_1 > a_2$. For some numerical solutions in the set-up above, where $a_1 = 1/4$ and $a_2 = 1/12$ or $1/30$, with $W_0 = 10^{-5}$ or 10^{-30} cf. [9].

²with instanton corrections consistently ignored for $\text{Im} z_1, \text{Im} z_2 \geq 1$

³With the first instanton correction one finds a near-by vacuum with $e^K |W|^2 = 1.379 \times 10^{-4}$.

⁴As actually $t = 6l$ all χ values in (4.2) are negative, so the flux influence can not change them to 1.

5 Integrating out the z_i and working with $K_{eff}(\tau)$

The action for (gauge neutral) chiral multiplets can be expressed in terms of a single real function G . The scalar potential becomes (with $G_{i\bar{j}} = \partial_i \partial_{\bar{j}} G$ and $G_i = \partial_i G$, $G^i = G^{i\bar{j}} G_{\bar{j}}$)

$$V = e^G \left(G^{i\bar{j}} G_i G_{\bar{j}} - 3 \right) = e^K \left(K^{i\bar{j}} D_i W \overline{D_{\bar{j}} W} - 3 W \overline{W} \right) \quad (5.1)$$

The index i runs over all chiral superfields, here the moduli and the dilaton. G can be, and usually is, (ambiguously) split as $G = K + \ln |W|^2$ into a real Kähler potential $K(z, \bar{z})$ and a holomorphic superpotential $W(z)$. The supersymmetry conditions are $D_i W = W_i + K_i W = W G_i = 0$. So, for $W \neq 0$, the supersymmetry conditions are in terms of G given by $G_i = 0$.

On the stability analysis in general

The stability analysis is based on the eigenvalues of the mass matrix. In the AdS case, one has to check whether the BF bound is satisfied. But in the case where one adds a term such that the vacuum energy becomes positive, one has to make sure that all eigenvalues of the mass matrix are actually positive. This must be done in a field basis where the kinetic terms are canonically normalized. However the eigenvalues in both bases are not the same but their signs are the same. If they are all positive in the original basis, they are also positive in the canonical basis (so a negative eigenvalue signals an instability).

To parallelize the treatment of the stability criterion of [7] let us recall also here the mass matrix, now in terms of G . First, the stationarity condition $\partial_k V = 0$ becomes

$$\partial_k V = e^G \left((G^i G_i - 3) G_k + (G^i \nabla_k G_i + G_k) \right) \quad (5.2)$$

At the minimum one gets the (kl) -symmetric (as $G_{i\bar{j}}$ is a Kähler metric) expression⁵

$$\begin{aligned} \partial_l \partial_k V|_{dV=0} &= e^G \left(\nabla_l G_k + \nabla_k G_l + (G^i G_i - 3) \nabla_l G_k + G^i \nabla_l \nabla_k G_i + (G_l + G^i \nabla_l G_i) G_k \right) \\ &= e^G \left(\nabla_l G_k + \nabla_k G_l + G^i \nabla_l \nabla_k G_i + (G^i G_i - 3) (\nabla_l G_k - G_l G_k) \right) \end{aligned} \quad (5.3)$$

For the mixed derivatives one finds (using $\nabla_{\bar{l}} \nabla_k G_i = R_{\bar{l}k}{}^j G_j$)⁶

$$\partial_{\bar{l}} \partial_k V|_{dV=0} = e^G \left(G_{k\bar{l}} + (G^i G_i - 3) G_{k\bar{l}} + G_k (G_{\bar{l}} + G^{\bar{j}} \nabla_{\bar{l}} G_{\bar{j}}) + \nabla_k G_i \nabla_{\bar{l}} G^i + R_{\bar{l}k}{}^j G_j G^i \right) \quad (5.4)$$

For a SUSY vacuum with $G_i = 0$ one has the simple expressions

$$\partial_l \partial_k V|_{\text{susy vacuum}} = -e^G \partial_k \partial_l G \quad (5.5)$$

$$\partial_{\bar{l}} \partial_k V|_{\text{susy vacuum}} = e^G \left(-2 G_{k\bar{l}} + G^{i\bar{j}} \partial_k G_i \partial_{\bar{l}} G_{\bar{j}} \right) \quad (5.6)$$

⁵For Minkowski vacua one is left with the first three terms (the last of these is missing in [17]).

⁶For Minkowski vacua one finds the first term and the last two terms, cf. [17].

5.1 Restricted preconsideration: the (z_i, τ) -sector

There are two equivalent ways to handle the integrating-out procedure. Either one eliminates the z_i in G (cf. below) and then operates, after reinserting them, with a G_{eff} ; alternatively one derives $W_{eff}^{non-holo}(\tau)$ from $D_i W_{flux}(z_i, \tau) = 0$ first and takes then, working in the G -formalism, $W_{eff}^{hol}(\tau) = 1$ and $K_{tot}(\tau) = K(\tau) + K(z_i(\tau)) + \ln |W_{eff}^{non-holo}|^2$ and the corresponding $G_{eff} = K_{tot}$; for this cf. [8] and the example treated by us below. Concretely from the expressions given earlier one gets then the z_i -elimination conditions

$$D_{z_i} W = \partial_{z_i} W + \partial_{z_i} K W = 0 \quad (5.7)$$

These equations allow to eliminate the z_i in $W_{flux}(z_i, \tau)$ and to get an effective superpotential $W_{eff}^{non-holo}(\tau)$ (this replaces the earlier constant W_0 when also τ was integrated out)⁷. One gets then, in this second way, the complete Kähler potential in τ as follows

$$K(\tau) = -\ln(\tau - \bar{\tau}) \quad (5.8)$$

$$K_{eff}(\tau) = K(z_i(\tau)) \quad (5.9)$$

$$K_{tot}(\tau) = K(\tau) + K_{eff}(\tau) + \ln |W_{eff}^{non-holo}(\tau)|^2 \quad (5.10)$$

Concerning the first procedure, as explained in the introduction, our strategy will be to solve the supersymmetry conditions for all the fields which appear in G . We first eliminate the z_i by solving, for a suitable choice of fluxes, $\partial_{z_i} G = 0$ where

$$G = K(\tau) + K(z_i) + \ln |W_{flux}(z_i, \tau)|^2 \quad (5.11)$$

The equations can be solved for the z_i and the solutions, which depend on τ , produce $G_{eff}(\tau)$ when reinserted into G . Two points are worth mentioning here. First, since we are working with the real function G , questions of holomorphicity of the superpotential do not arise. This is an issue, since the SUSY conditions $D_{z_i} W = 0$ are not holomorphic and would lead to a non-holomorphic W_{eff} . Secondly, one also has to insert the solutions $z_i(\tau)$ into $K(z_i)$ and not merely into W_{flux} .

Note that, for $W \neq 0$, both procedures are equivalent as the respective elimination conditions are $G_i = 0$ and $D_i W = 0$.

Before we come to the main issue of this note, the consideration of the case with two Kähler parameters, we give first the procedure in the generic one parameter case, following [7] but including $K(z_i(\tau))$ and $\ln |W_{eff}^{non-holo}(\tau)|^2$. We will see that including the $\mathcal{T}$ -sector leads to a slight change in the procedure.

⁷the fluxes chosen earlier which lead to the concrete expressions for W_{flux} gave a minimum at $z_1 = z_2 = i, \tau = 3i$ in the procedure where τ is also integrated out; we can, of course, choose other fluxes.

5.2 Full $(z_i, \tau, \mathcal{T})$ -sector: the generic one parameter case

In the generic set-up with one Kähler parameter one would start in analogy to [7] with

$$W = W_{flux}(z_i, \tau) + W^{(\mathcal{T})} = A(z_i) + \tau B(z_i) + C e^{-a\mathcal{T}} \quad (5.12)$$

with the Kähler potential (where $K(\mathcal{T}) = -2 \ln(\mathcal{T} + \bar{\mathcal{T}})^{3/2}$)

$$K = -\ln(\tau - \bar{\tau}) + K(z_i) + K(\mathcal{T}) \quad (5.13)$$

Integrating out the z_i by $G_i = 0$ resp. $G_i \cdot W = D_i W = D_i(W_{flux} + C e^{-a\mathcal{T}}) = 0$ gives

$$D_i W = A_i + \tau B_i + K_i(W_{flux} + C e^{-a\mathcal{T}}) = 0 \quad (5.14)$$

where compared with the previous (5.7) the exponentially suppressed perturbation term $K_i W^{(\mathcal{T})}$ has arisen. Therefore now the previous $z_i = z_i(\tau)$ becomes here $z_i = z_i(\tau, \mathcal{T}) = z_i(\tau) + \delta W^{(\mathcal{T})} + \epsilon \bar{W}^{(\bar{\mathcal{T}})} + \dots$, cf. [8]. So one is led to use a $W_{eff}^{holo}(\tau, \mathcal{T}) \equiv 1$ and the Kähler potential

$$\begin{aligned} G_{eff} = K_{eff} = & -\ln(\tau - \bar{\tau}) + K(z_i(\tau, \mathcal{T})) - 3 \ln(\mathcal{T} + \bar{\mathcal{T}}) \\ & + \ln |A(z_i(\tau, \mathcal{T})) + \tau B(z_i(\tau, \mathcal{T})) + C e^{-a\mathcal{T}}|^2 \end{aligned} \quad (5.15)$$

Note that to get G_{eff} in (5.15), it would have been again equivalent (for $W \neq 0$) to start with the full $G^{full} = -\ln(\tau - \bar{\tau}) + K(z_i) + K(\mathcal{T}) + \ln |W_{flux}(z_i, \tau) + W^{(\mathcal{T})}|^2$, solve there $G_i^{full} = 0$ for the $z_i(\tau, \mathcal{T})$ and reinserting into G^{full} , for one has $D_i W_{flux} = W G_i^{full}$.

Note in passing that the procedure described is not the same as doing the previous integrating-out procedure just in the (z_i, τ) -sector with $W_{eff}^{holo}(\tau) \equiv 1$ and just adding the $\mathcal{T}$ -sector. This leads to the following point: in the two-step analysis of KKLT all moduli of $W_{flux}(z_i, \tau)$ were integrated out; this left behind just a W_0 when afterwards the further $W^{(\mathcal{T})}$ was included. However, as [7] pointed out, this procedure may not be justified as the masses of τ and $\mathcal{T}$ can be comparable; so in [7] just the z_i were integrated out, leaving a $W_{eff}(\tau)$ behind instead of the constant W_0 . This procedure, as outlined in [8] and described also below, has to be supplemented, at least, with the inclusion of $K(z_i(\tau))$ and a proper treatment of $W_{eff}^{non-holo}(\tau)$. As we described above, even including these points, there would be still a remnant of the linkage of τ with the z_i , if $z_i(\tau)$ would be assumed to be just a function of τ (what would arise from integrating it out while considering just $W_{flux}(z_i, \tau)$, and including $W^{(\mathcal{T})}(\mathcal{T})$ only afterwards) instead of determining a $z_i(\tau, \mathcal{T})$ from the full $W = W_{flux}(z_i, \tau) + W^{(\mathcal{T})}(\mathcal{T})$.

6 The two-parameter example

Take the flux components with the general full magnetic sector

$$(e_R^a | m_R^a) = (0, g, h | -e, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | e', c, d) \quad (6.1)$$

Concerning the two special magnetic fluxes e and e' which contribute in W_{flux} only by adding a constant $E = e + e'\tau$, which is independent of the complex structure moduli, we will set at first $e = e' = 0$. We will employ the following notation (and $z_k = x_k + iy_k$)

$$A := a + \tau c = A_1 + iA_2 \quad , \quad B := b + \tau d = B_1 + iB_2 \quad (6.2)$$

$$Z := 3z_1 + z_2 = X + iY \quad , \quad y := y_2 \quad (6.3)$$

$$p := \frac{a - 3b}{3} \quad , \quad q := \frac{c - 3d}{3} \quad (6.4)$$

$$W^{(T)} = \sum_{k=1}^2 W^k = \sum_{k=1}^2 C_k e^{-a_k T_k} \quad (6.5)$$

We will always stick to the case $q = 0$, i.e. $c = 3d$ (note that this was also satisfied in the flux-choice (4.1)); we exclude the case $c = 0 = d$ where things collapse trivially.

We will then write the two SUSY conditions $D_{z_i} W = 0$ which allow us to eliminate the z_i and write $W_{eff}(\tau)$. The way we proceed to do this in practice amounts to writing W_{flux} (with the help of the SUSY conditions) purely as function of τ and only one of the four real variables X, Y, x_2, y , concretely either Y or y , where the latter furthermore depends in a simple polynomial way on τ .

We then proceed and include the $\mathcal{T}_k$ -sector. For that purpose we generalize the above set-up first to include fluxes $m_R^0 = -e, m_{NS}^0 = e'$ and the corresponding contribution $E = e + e'\tau = E_1 + iE_2$ in W_{flux} . The latter will be used then to mimic the $W^{(T)}$. This will be described more fully below in our main example, the case II. In total the following cases will be described

$$\underline{\text{CASE I}} \quad g = 0 \quad , \quad h = 0$$

$$\underline{\text{CASE II}} \quad g \neq 0 \quad , \quad h = 0$$

$$\underline{\text{CASE III}} \quad g \neq 0 \quad , \quad h = -3g$$

We will get an explicit expression for W_{eff} in all 3 cases. In the case II, which constitutes our main example, we will proceed and analyse the SUSY conditions completely in closed analytical form and show that no SUSY solution exists. As the main issue here is the explicit derivation of W_{eff} and the concrete analytical treatment of the ensuing SUSY conditions we give this in some detail so that one can follow the line of derivation.

6.1 The case I: $g = h = 0$

We will at first assume that $g = h = 0$. Although this leads to the somewhat degenerate case of $L = 0$ we mention this case first as some equations appear here first in a somewhat simpler form than in our main example case II. This leads to

$$W_{flux} = az_1 + bz_2 + \tau(cz_1 + dz_2) = Az_1 + Bz_2 = \frac{A}{3}Z - pz_2 \quad (6.6)$$

which gives as elimination equations (where $z_k = x_k + iy_k$)

$$D_{z_1}W = 0 \implies 2i\frac{A}{3} = \frac{\frac{1}{3}(3y_1 + y_2)^2}{y_1(3y_1^2 + 3y_1y_2 + y_2^2) + i\xi} (Az_1 + Bz_2) \quad (6.7)$$

$$D_{z_2}W = 0 \implies 2iB = \frac{y_1(3y_1 + 2y_2)}{y_1(3y_1^2 + 3y_1y_2 + y_2^2) + i\xi} (Az_1 + Bz_2) \quad (6.8)$$

This yields (for $Y \neq 0$, as is needed to keep things nontrivial) the compatibility equation

$$\frac{A}{3}(Y^2 - y^2) = BY^2 \quad (6.9)$$

As the y_k are real and $A_2/3 = B_2$ the imaginary part here gives $y = 0$, with $pY^2 = 0$ as remaining relation; one gets therefore also $p = 0$ and the expressions $W_{flux} = \frac{A}{3}Z$ and

$$W_{flux} = 2i\frac{A}{3} \frac{3y_1^3 + i\xi}{3y_1^2} \quad (6.10)$$

The resulting relation $Z = 2i\frac{3y_1^3 + i\xi}{3y_1^2}$ gives $X = 0$ and $Y = 2\frac{Y^3 + 9i\xi}{3Y^2}$ or

$$Y = \sqrt[3]{2 \cdot 9i\xi} \quad (\iff Y^3 + 3CY^2 - 2 \cdot 9i\xi = 0 \text{ with } C := 0) \quad (6.11)$$

$$W_{eff}(\tau) = \frac{A}{3}Z = iAy_1 = i(a + c\tau)\sqrt[3]{\frac{2}{3}i\xi} \quad (6.12)$$

(Note that, if one would force now also the third condition (usual KKLT procedure)

$$D_\tau W_{flux} = 0 \implies 2idZ = \frac{1}{\tau_2} (Az_1 + Bz_2) \quad (6.13)$$

one would get $2id\tau_2 = \frac{a+c\tau}{3}$, i.e. $\tau = -\frac{a}{c}$ with $\tau_2 = 0$, i.e. no (physical) solution.)

Although this example is somewhat degenerate ($L = 0$) let us proceed and include the $\mathcal{T}_k$ -sector. So we generalize the above to include fluxes $m_R^0 = -e, m_{NS}^0 = e'$ and the corresponding contribution $E = e + e'\tau = E_1 + iE_2$ in W_{flux} . Then the trivial C above changes to an E -dependent $\tilde{C}$ (we use now the abbreviated notation $\mathcal{A} := A/3$).

One gets $W_{flux} = \mathcal{A}Z + E$ and equating with (6.10) gives for the real and imaginary part

$$X = -\frac{\mathcal{A}_1 E_1 + \mathcal{A}_2 E_2}{\mathcal{A}_1^2 + \mathcal{A}_2^2} \quad (6.14)$$

$$Y^3 + 3\tilde{C}Y^2 - 2 \cdot 9i\xi = 0 \quad (\tilde{C} := \frac{\mathcal{A}_1 E_2 - \mathcal{A}_2 E_1}{\mathcal{A}_1^2 + \mathcal{A}_2^2}) \quad (6.15)$$

With this cubic determination equation one gets for the effective Kählerpotential (up to an additive constant) and the effective superpotential (with $E := W^{(T)}$) and G -function

$$K_{eff}(\tau, \mathcal{T}_k) = -\ln(Y^3 - y^3 + 9i\xi) = -2\ln Y - \ln \mathcal{B} \quad (6.16)$$

$$W_{eff}(\tau, \mathcal{T}_k) = \mathcal{A}(X + iY) + E = \frac{2i}{3} \mathcal{A} \frac{Y^3 + 9i\xi}{Y^2} = i\mathcal{A}\mathcal{B} \quad (6.17)$$

$$G_{eff}(\tau, \mathcal{T}_k) = K_{eff}(\tau, \mathcal{T}_k) + \ln |W_{eff}(\tau, \mathcal{T}_k) + W^{(T)}|^2 - \ln(\tau - \bar{\tau}) + K(\mathcal{T}_k) \quad (6.18)$$

Here we use the following notation

$$\mathcal{B} = Y + \tilde{C} \quad , \quad s_k = (-1)^k \frac{3}{2} \frac{t_k^{1/2}}{t_2^{3/2} - t_1^{3/2}} \quad (6.19)$$

$$\Gamma = \mathcal{B} \frac{\mathcal{A}\bar{\mathcal{A}}\mathcal{B} + (\mathcal{A}_1 \text{Im } W - \mathcal{A}_2 \text{Re } W)}{(\mathcal{A}_1 \mathcal{B} + \text{Im } W)^2 + (-\mathcal{A}_2 \mathcal{B} + \text{Re } W)^2} \quad , \quad \Gamma' = \frac{-i\bar{\mathcal{A}}\mathcal{B} + \overline{W^{(T)}}}{(\mathcal{A}_1 \mathcal{B} + \text{Im } W)^2 + (-\mathcal{A}_2 \mathcal{B} + \text{Re } W)^2} \quad (6.20)$$

Note that one still has $y = 0$ as before. Furthermore $Y \neq 0$ and the effective Kähler potential gives from $Y^3 - y^3 + 9i\xi = Y^3 + 9i\xi = \frac{3}{2}Y^2(Y + \tilde{C})$ that also $\mathcal{B} \neq 0$.

Furthermore one has the following relations (l stands for k or τ)

$$Y_l(Y + 2\tilde{C}) = -\tilde{C}_l Y \quad (6.21)$$

$$\tilde{C}_k = 3i \frac{a_k W^k}{2A} \quad , \quad \tilde{C}_\tau = 3i \frac{c W^{(T)}}{2A^2} \quad (6.22)$$

$$Y_l = \tilde{C}_l \frac{-Y}{Y + 2\tilde{C}} \quad , \quad \mathcal{B}_l = \tilde{C}_l \frac{2\tilde{C}}{Y + 2\tilde{C}} \quad (6.23)$$

From G_{eff} (in the following denoted by G) one gets as SUSY conditions

$$G_k = -2 \frac{Y_k}{Y} + (2\Gamma - 1) \frac{\mathcal{B}_k}{\mathcal{B}} - a_k W^k \Gamma' + s_k = 0 \quad (6.24)$$

$$G_\tau = -2 \frac{Y_\tau}{Y} + (2\Gamma - 1) \frac{\mathcal{B}_\tau}{\mathcal{B}} + i \frac{c}{3} \mathcal{B} \Gamma' + \frac{i}{2\tau_2} = 0 \quad (6.25)$$

For a full treatment of such a set of equations we refer to the case II below. As the case I is somewhat degenerate ($L = 0$) we are content here to derive W_{eff} (for more details on the eliminations following from the detailed treatment of the SUSY equations, along the lines of the complete procedure as in case II, cf. the appendix).

6.2 The case II: $g \neq 0, h = 0$

For an example where $L = cg/2 \neq 0$ take (again in the case $A_2 = 3B_2$, i.e.⁸ $c = 3d$)

$$(e_R^a | m_R^a) = (0, g, 0 | 0, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | 0, c, d) \quad (6.26)$$

which gives (with $A = A_1 + iA_2 := a + c\tau, B = B_1 + iB_2 := b + d\tau$)

$$W_{flux} = gF_1 + az_1 + bz_2 + \tau(cz_1 + dz_2) = g\left(-\frac{1}{2}Z^2 + \frac{3}{2}Z + \frac{17}{4}\right) + Az_1 + Bz_2 \quad (6.27)$$

We use the following abbreviations (for $g \neq 0$)

$$C := \frac{A_1 + \frac{9}{2}g}{3p} \quad , \quad \beta = \frac{B_2}{g} \quad (6.28)$$

Useful relations are

$$Az_1 + Bz_2 = \frac{A}{3}Z - pz_2 \quad (6.29)$$

$$9y_1(3y_1^2 + 3y_1y_2 + y_2^2) = Y^3 - y_2^3 \quad (6.30)$$

One gets as elimination equations $D_{z_1}W = 0$ and $D_{z_2}W = 0$

$$\left[\frac{A}{3} - g\left(Z - \frac{3}{2}\right)\right] = \frac{3}{2i} \frac{Y^2}{Y^3 - y^3 + 9i\xi} \left(gF_1 + Az_1 + Bz_2\right) \quad (6.31)$$

$$\left[B - g\left(Z - \frac{3}{2}\right)\right] = \frac{3}{2i} \frac{Y^2 - y^2}{Y^3 - y^3 + 9i\xi} \left(gF_1 + Az_1 + Bz_2\right) \quad (6.32)$$

(recall we denote y_2 just by y). Now the imaginary and real part of the compatibility equation

$$\left[\frac{A}{3} - g\left(Z - \frac{3}{2}\right)\right](Y^2 - y^2) = \left[B - g\left(Z - \frac{3}{2}\right)\right]Y^2 \quad (6.33)$$

yield for $y \neq 0$ and $g \neq 0$ the eliminations

$$Y = \beta \quad , \quad X = \frac{p}{g} \left(C - \frac{\beta^2}{y^2}\right) \quad (6.34)$$

Finally we have to solve the imaginary and real part of (6.31), say, which gives, noting that the big fraction on the right hand side is real and that (by explicit evaluation)

$$\text{Im } W_{flux} = p(C\beta - y) \quad (6.35)$$

finally the cubic equation

$$y^3 - 3C\beta y^2 + 2(\beta^3 + 9i\xi) = 0 \quad (6.36)$$

⁸We assume $c \neq 0 \neq d$ to retain a proper τ -dependence in W_{flux} after integrating out the z_i .

Let us remark on the cubic equation occuring here.

1) (6.36) is of course easily solved in general. If one would be interested only in purely imaginary τ (note that $\tau_2 = s = \text{Re } S$ under $\tau =: iS$, where $\tau = \tau_1 + i\tau_2$), i.e. $A_1 = a, B_1 = b$, and furthermore in the special case $C = 0$, i.e. $a = -\frac{9}{2}g$, then

$$W_{eff}(\tau_2) = -ipy = i(b + \frac{3}{2}g) \left(-2 \left(\frac{d^3}{g^3} \tau_2^3 + 9i\xi \right) \right)^{1/3} \quad (6.37)$$

2) In the general case one gets for $r := y - C\beta$ with $W_{eff} = -ipr$ the equation

$$r^3 + Pr + Q = r^3 - 3C^2\beta^2r + 2 \left((1 - C^3)\beta^3 + 9i\xi \right) = 0 \quad (6.38)$$

(note $\beta, C, i\xi, P, Q \in \mathbf{R}$) with the three solutions given by the Cardano formula where one solution is always real and all three are real for $0 \geq D := (Q/2)^2 + (P/3)^3$.

Now let us come back to the use of this information for our main goal, whic is to derive the supersymmetry conditions from the effective G -function. One now has a $K_{eff}(\tau) = K(z_i(\tau))$ which can be written in various equivalent ways

$$K_{eff}(\tau) = -\ln \left(\beta^3 + 9i\xi - y^3 \right) - \ln \frac{4i}{9} \quad (6.39)$$

$$= -\ln \left(\beta^3 + 9i\xi - C\beta y^2 \right) - \ln \frac{4i}{3} \quad (6.40)$$

$$= -\ln y^2 - \ln(y - C\beta) - \ln \frac{-2i}{3} \quad (6.41)$$

giving in total (up to the constant $-\ln \frac{-2i}{3}$)

$$K_{tot}(\tau) = -\ln(\tau - \bar{\tau}) - 2\ln y - \ln(y - C\beta) \quad (6.42)$$

Note that, in contrast to the original piece $-\ln(\tau - \bar{\tau})$, the new, full $K_{tot}(\tau)$ depends not just on τ_2 as the coefficient C (which determines together with β the y) depends on τ_1 .

Because of its non-holomorphicity one gets (for $r \in \mathbf{R}$) from W_{eff} where

$$W_{eff}(\tau) = ip(\beta C - y) \quad (6.43)$$

the further contribution (up to the constant $2\ln p$)

$$\ln |W_{eff}^{non-holo}(\tau)|^2 = 2\ln(y - C\beta) \quad (6.44)$$

Up to now we have followed the treatment just in the (z_i, τ) -sector (cf. our discussion in the subsection on the corresponding restricted reconsideration). Now we have to properly enhance these results by going to the consideration of the full $(z_i, \tau, \mathcal{T}_k)$ -sector.

Including the $\mathcal{T}_i$ -sector

Up to now we have expressed the z_i as functions of τ from $D_i W_{flux} = 0$. According to the discussion in sect. 5.2 we want actually to obtain $z_i(\tau, \mathcal{T}_i)$ from $D_i(W_{flux} + W^{(\mathcal{T})}) = 0$. For this we will 1) give the explicit expressions $z_i(\tau)$, 2) generalize our flux-example to include a constant flux and give there the $z_i(\tau)$, 3) interpret *formally* the additional term $W^{(\mathcal{T})}$, which is constant in τ , as such an additional flux term and 4) give thereby the full $z_i(\tau, \mathcal{T}_i)$.

1) Note first that $\text{Re}W_{flux} = 0$ from (6.31) gives

$$x_1 = \frac{g}{A_1 - 3B_1} \left(\frac{1}{2}X^2 + \frac{1}{2}\beta^2 - \left(\frac{3}{2} + \frac{B_1}{g}\right)X - \frac{17}{4} \right) \quad (6.45)$$

Therefore the two variables $Z = 3z_1 + z_2 = X + iY$ and $z_1 = x_1 + iy_1$ are completely determined as functions of τ and $y = y_2$ (and therefore as functions of τ alone): for X and Y this was given above, and for z_1 it is, together with $y_1 = (Y - y_2)/3$, given here.

2) Now let us generalize this set-up by including an additional constant (in the z_i) contribution in W_{flux} . For this we start with the enhanced flux vector

$$(e_R^a | m_R^a) = (0, g, 0 | -e, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | e', c, d) \quad (6.46)$$

which gives (with $E = e + e'\tau = E_1 + iE_2$) the flux-superpotential $W'_{flux} = W_{flux} + E$

$$W'_{flux} = gF_1 + Az_1 + Bz_2 + E \quad (6.47)$$

In this generalized situation (with $p\tilde{E} = E$) the elimination of y reads now (the expressions (6.34) for X and Y , coming from (6.33), have still just g and C and remain the same)

$$y^3 - 3(\beta C + \tilde{E}_2)y^2 + 2(\beta^3 + 9i\xi) = 0 \quad (6.48)$$

Formally one could even absorb the $\tilde{E}_2 =: \tilde{e}\tau_2 = pe'\tau_2$ in a $\tilde{C}$ built with an $\tilde{g} := g(1 + \frac{2e'}{3d})$, i.e., $\beta C + \tilde{E}_2 = \beta\tilde{C}$ (not to be used in (6.34)). Finally one gets the shift $x'_1 = x_1 - \frac{E_1}{a-3b}$.

3) Now the elimination condition for $z_i = z_i(\tau, \mathcal{T}_i)$

$$\partial_i W_{flux} + K_i(W_{flux} + W^{(\mathcal{T})}) = 0 \quad (6.49)$$

can formally be interpreted as the elimination condition $\partial_i W'_{flux} + K_i W'_{flux} = 0$ for $z_i = z_i(\tau)$ with respect to an enhanced flux-superpotential $W'_{flux} = W_{flux} + E$ where the latter will be interpreted formally as $W^{(\mathcal{T})}$.

4) Altogether we get thereby the searched for expressions $z_i(\tau, \mathcal{T}_i)$ as the $z'_i(\tau)$ in the previous set-up, generalized by putting formally $E := W^{(\mathcal{T})}$.

6.2.1 The SUSY conditions for the Kähler moduli $\mathcal{T}_i$ and the dilaton τ

Let us now apply the previous considerations concerning G_{eff} in (5.15) to our two-parameter model. In the end we will discuss stable minima for V in (5.1). One finds, for⁹ y in (6.48), with the help of (6.41) that (up to an additive constant)

$$K_{eff}(\tau, \mathcal{T}_i) = K(z_i(\tau, \mathcal{T}_i)) = K(z'_i(\tau)) = -\ln y^2 - \ln(y - \beta\tilde{C}) \quad (6.50)$$

Similarly one has with $E = W^{(T)}$, $E = p\tilde{E}$ and $\beta C + \tilde{E}_2 = \beta\tilde{C}$ where $\tilde{C}$ is a function not only of τ_1 , as in (6.28), but also of the $\mathcal{T}_i$ (with $W^{(T)}(\mathcal{T}_i) = \sum C_k e^{-a_k \mathcal{T}_k}$)

$$\tilde{C} = \frac{a + c\tau_1 + \frac{9}{2}g + \frac{3g}{d\tau_2} \text{Im}W^{(T)}(\mathcal{T}_i)}{a - 3b} \quad (6.51)$$

(for simplicity we will assume $C_i \in \mathbf{R}$) the following expression

$$\begin{aligned} W_{eff}(\tau, \mathcal{T}_i) = W_{flux}(z_i(\tau, \mathcal{T}_i), \tau) &= W_{flux}(z'_i(\tau)) = i \left[p(\beta C - y) + \text{Im}W^{(T)} \right] \\ &= ip(\beta\tilde{C} - y) \end{aligned} \quad (6.52)$$

Therefore we find altogether for the G_{eff} in (5.15) (up to an additive constant)

$$\begin{aligned} G_{eff} &= -\ln(\tau - \bar{\tau}) + K_{eff}(\tau, \mathcal{T}_i) + \ln \left| W_{eff}(\tau, \mathcal{T}_i) + W^{(T)}(\mathcal{T}_i) \right|^2 + K(\mathcal{T}_i) \quad (6.53) \\ &= -\ln(\tau - \bar{\tau}) - 2\ln y - \ln(y - \beta\tilde{C}) + \ln \left| ip(\beta\tilde{C} - y) + \sum_{i=1}^2 C_i e^{-a_i \mathcal{T}_i} \right|^2 \\ &\quad - 2\ln \left((\mathcal{T}_2 + \bar{\mathcal{T}}_2)^{3/2} - (\mathcal{T}_1 + \bar{\mathcal{T}}_1)^{3/2} \right) \end{aligned} \quad (6.54)$$

from which one gets the three *SUSY* conditions $G_i = 0$. When searching for solutions one has to satisfy also $L = N_{flux} = cg/2 \leq e(X_4)/24 = 273$ and 129 for $a_2 = 1/12$ and $1/30$, respectively. (When using $W^{(T)}$ numerically one has to make the shift $a_i \rightarrow 2\pi a_i$.)

Using $\beta = \frac{d}{g}\tau_2$, and $\beta\tilde{C} = \beta C + \frac{1}{p}\text{Im}W^{(T)}$ one has

$$\beta_\tau = \frac{d}{2ig} \quad , \quad (\beta\tilde{C})_\tau = \beta_\tau C + \beta \frac{c/2}{a - 3b} \quad (6.55)$$

$$\beta_{\mathcal{T}_i} = 0 \quad , \quad (\beta\tilde{C})_{\mathcal{T}_k} = \frac{i}{2p} a_k C_k e^{-a_k \mathcal{T}_k} \quad (6.56)$$

From (6.48) one finds (l is τ or $\mathcal{T}_i$)

$$y_l(y - 2\beta\tilde{C}) = (\beta\tilde{C})_l y - 2 \frac{\beta_l \beta^2}{y} \quad (6.57)$$

⁹i.e., the y in (6.48) can be understood as the ordinary y in (6.36) with $C \rightarrow \tilde{C}$

Evaluating the SUSY conditions

For evaluation of the SUSY conditions we use the following abbreviations

$$\mathcal{B} = \beta\tilde{C} - y \quad , \quad s_k = -(-1)^k \frac{3}{2} \frac{t_k^{1/2}}{t_2^{3/2} - t_1^{3/2}} \quad , \quad W^T = \sum_{k=1}^2 W^k = \sum_{k=1}^2 C_k e^{-a_k(t_k + i\theta_k)} \quad (6.58)$$

$$\Gamma = p\mathcal{B} \frac{p\mathcal{B} + \text{Im } W^T}{(p\mathcal{B} + \text{Im } W^T)^2 + (\text{Re } W^T)^2} \quad , \quad \Gamma' = \frac{-i(p\mathcal{B} + \text{Im } W^T) + \text{Re } W^T}{(p\mathcal{B} + \text{Im } W^T)^2 + (\text{Re } W^T)^2} \quad (6.59)$$

($\mathcal{B}, s_k, \Gamma$ are real quantities). One gets for the SUSY conditions

$$G_k = -2\frac{y_k}{y} + (2\Gamma - 1)\frac{\mathcal{B}_k}{\mathcal{B}} - a_k W^k \Gamma' + s_k = 0 \quad (6.60)$$

$$G_\tau = -2\frac{y_\tau}{y} + (2\Gamma - 1)\frac{\mathcal{B}_\tau}{\mathcal{B}} + \frac{i}{2\tau_2} = 0 \quad (6.61)$$

Note that $y \neq 0$ or else one would have $\beta^3 + 9i\xi = 0$ by the cubic equation and $K(z_i) = \ln(Y^3 - y^3 + 9i\xi) = \ln(\beta^3 - y^3 + 9i\xi)$ would degenerate. Note furthermore that $y - 2\beta\tilde{C} \neq 0$ or else (6.57) would give $(\beta \frac{c/2}{a-3b} + \frac{d}{2ig}C)y^2 = 2\frac{d}{2ig}\beta^2$, i.e. $c = 0 = d$ from the real part, violating our assumption. Applying (6.57) to $l = k$ likewise gives the immediate contradiction $C_k = 0$.

For the following it is useful to collect some expressions (subscript k indicates $\partial_{\mathcal{T}_k}$)

$$(\beta\tilde{C})_k = \frac{i}{2p} a_k W^k \quad (6.62)$$

$$y_k = (\beta\tilde{C})_k \frac{y}{y - 2\beta\tilde{C}} \quad , \quad \mathcal{B}_k = -(\beta\tilde{C})_k \frac{2\beta\tilde{C}}{y - 2\beta\tilde{C}} \quad (6.63)$$

As the splitting in real and complex parts will be crucial below note that here the fractions are real so that the real and imaginary parts of y_k and $\mathcal{B}_k$ go with the corresponding real and imaginary parts of $(\beta\tilde{C})_k$ (times the fraction).

Similarly one gets in the τ -sector

$$(\beta\tilde{C})_\tau = \beta \frac{c/2}{3p} - i \frac{d}{2g} C \quad (6.64)$$

$$\text{Re } y_\tau = \text{Re } (\beta\tilde{C})_\tau \frac{y}{y - 2\beta\tilde{C}} \quad , \quad \text{Re } \mathcal{B}_\tau = -\text{Re } (\beta\tilde{C})_\tau \frac{2\beta\tilde{C}}{y - 2\beta\tilde{C}} \quad (6.65)$$

$$\text{Im } y_\tau = -\frac{d}{2g} \frac{Cy^2 - 2\beta^2}{y(y - 2\beta\tilde{C})} \quad , \quad \text{Im } \mathcal{B}_\tau = -\frac{d}{2g} \frac{2\beta^2 - 2\beta\tilde{C}Cy}{y(y - 2\beta\tilde{C})} \quad (6.66)$$

Now let us consider the real and imaginary parts of $G_k = 0$ and $G_\tau = 0$

$$-2\frac{Re y_k}{y} + (2\Gamma - 1)\frac{Re \mathcal{B}_k}{\mathcal{B}} - a_k \frac{Re [W^k(-ip\mathcal{B} + \bar{W})]}{|ip\mathcal{B} + W|^2} = -s_k \quad (6.67)$$

$$-2\frac{Im y_k}{y} + (2\Gamma - 1)\frac{Im \mathcal{B}_k}{\mathcal{B}} - a_k \frac{Im [W^k(-ip\mathcal{B} + \bar{W})]}{|ip\mathcal{B} + W|^2} = 0 \quad (6.68)$$

$$-2\frac{Re y_\tau}{y} + (2\Gamma - 1)\frac{Re \mathcal{B}_\tau}{\mathcal{B}} = 0 \quad (6.69)$$

$$-2\frac{Im y_\tau}{y} + (2\Gamma - 1)\frac{Im \mathcal{B}_\tau}{\mathcal{B}} = -\frac{1}{2\tau_2} \quad (6.70)$$

(here $W := W^T$). Let us draw some consequences (we had $C_i \in \mathbf{R}$ for simplicity)

$$2\mathcal{B} = -2(2\Gamma - 1)\beta\tilde{C} \quad (\implies y = 2\Gamma\beta\tilde{C}) \quad (6.71)$$

$$Re W^k = 0 \implies \theta_k = \pm \frac{\pi}{a_k} \text{ and } Re W = 0 \quad (\implies \Gamma = \frac{p\mathcal{B}}{p\mathcal{B} + Im W}) \quad (6.72)$$

$$\frac{s_k}{a_k} = \frac{Im W^k}{p\mathcal{B} + Im W} = \frac{\pm C_k e^{-a_k t_k}}{p\mathcal{B} + \sum \pm C_j e^{-a_j t_j}} \quad (\implies \sum \frac{s_k}{a_k} = \frac{Im W}{p\mathcal{B} + Im W}) \quad (6.73)$$

$$\tilde{C}y^2 = -2\beta^2 \quad (\stackrel{(6.36)}{\implies} y^3 + 2(4\beta^3 + 9i\xi) = 0) \quad (6.74)$$

Proof of (6.71) - (6.74)

(6.69) implies (6.71). This makes the first two terms in (6.68) cancel

$$0 = \frac{a_k}{2p} Re W^k \left(-2\frac{1}{y - 2\beta\tilde{C}} + (2\Gamma - 1)\frac{-2\beta\tilde{C}}{\mathcal{B}(y - 2\beta\tilde{C})} \right) - a_k \frac{Im [W^k(-ip\mathcal{B} + \bar{W})]}{|ip\mathcal{B} + W|^2} \quad (6.75)$$

which proves (6.72). With (6.63) and (6.71) one gets that in (6.67) the first two terms cancel so that one gets the following relation implying (6.73) using $Re W = 0$

$$\frac{s_k}{a_k} = \frac{Re [W^k(-ip\mathcal{B} + \bar{W})]}{|ip\mathcal{B} + W|^2} \quad (6.76)$$

Rewriting (6.70) with (6.71) and multiplying by $-2\tau_2 y^2 \tilde{C}$ gives (6.74). $\square$

By (6.74) one gets y as function of β (i.e. of τ_2); similarly for $\tilde{C}$, $\mathcal{B}$ and Γ (let $\zeta := 9i\xi$)

$$y = [-2(4\beta^3 + \zeta)]^{1/3} \quad (6.77)$$

$$\tilde{C} = -\frac{2\beta^2}{y^2} = -\frac{2\beta^2}{[-2(4\beta^3 + \zeta)]^{2/3}} \quad (6.78)$$

$$\mathcal{B} = \beta\tilde{C} - y = [-2(4\beta^3 + \zeta)]^{1/3} \left(\frac{\beta^3}{(4\beta^3 + \zeta)} - 1 \right) \quad (6.79)$$

$$\Gamma = \frac{y}{2\beta\tilde{C}} = \frac{4\beta^3 + \zeta}{2\beta^3} \quad (6.80)$$

So there remain three equations for the unknowns t_1, t_2, τ_2 . When one has obtained t_1, t_2, τ_2 one will get τ_1 from the definition (6.51) of $\tilde{C}$.

One remains with the three equations (for (6.82) note $\sum \frac{s_k}{a_k} = \frac{Im W}{p\mathcal{B} + Im W} = 1 - \Gamma$)

$$\frac{s_k}{a_k} = \frac{Im W^{(k)}}{p\mathcal{B} + Im W} \quad (6.81)$$

$$\mathcal{S} := \sum \frac{s_k}{a_k} = -\frac{2\beta^3 + \zeta}{2\beta^3} \quad (6.82)$$

Now let us decouple the t_i sector from the τ_2 sector. (6.81) gives first

$$-\sqrt{\frac{t_2}{t_1}} = \frac{s_2}{s_1} = \frac{a_2}{a_1} \frac{\pm_2 C_2 e^{-a_2 t_2}}{\pm_1 C_1 e^{-a_1 t_1}} \quad (6.83)$$

$$\mathcal{S} = \frac{Im W}{p\mathcal{B} + Im W} \quad (\text{with } \mathcal{B} = \sqrt[3]{-2\zeta \frac{\mathcal{S}-1}{\mathcal{S}+1} \frac{\frac{1}{2}-\mathcal{S}}{\mathcal{S}-1}}) \quad (6.84)$$

For (6.84) note (6.79) and that (6.82) gives $\beta^3 = -\frac{1}{2} \frac{\zeta}{1+\mathcal{S}}$; the latter relation will give τ_2 once we have solved the two equations (6.83) and (6.84) for the t_i .

These equation can also be written as (note $\mathcal{S} = \sum \frac{s_k}{a_k}$ and $Im W = \sum Im W^{(k)}$)

$$\frac{s_2/a_2}{s_1/a_1} = \frac{Im W^{(2)}}{Im W^{(1)}} \quad (6.85)$$

$$Im W = p \sqrt[3]{-2\zeta} \frac{\mathcal{S}(\mathcal{S} - \frac{1}{2})}{\mathcal{S}^2 - 1} \quad (6.86)$$

Obviously these equations could possibly have the trivial solution that the common proportionality factor in (6.85) is -1 (if that value can be realised); this then means however that $\mathcal{S} = 0 = Im W$ and $\Gamma = 1$, so that $y - 2\beta\tilde{C} = 0$, according to (6.80), contrary to hypothesis (it would imply $c = 0 = d$).

Let us recall finally also the explicit expressions for the independent variables t_k

$$s_k = (-1)^{k+1} \frac{3}{2} \frac{t_k^{1/2}}{t_2^{3/2} - t_1^{3/2}} \quad , \quad t_k = -\frac{3}{2} \frac{s_k^2}{s_1^3 + s_2^3} \quad ; \quad Im W^{(k)} = \pm_k C_k e^{-a_k t_k} \quad (6.87)$$

The solution to (6.85), (6.86) is (we take $\pm_k = +$, it can be absorbed in C_k anyway)

$$a_k t_k = \frac{a_k^3}{a_2^3 - a_1^3} L \quad \implies \quad \frac{s_k}{a_k} = (-1)^{k+1} \frac{3}{2L} \quad , \quad Im W^{(k)} = (-1)^{k+1} \frac{C_1^{\frac{a_2^3}{a_2^3 - a_1^3}}}{(-C_2)^{\frac{a_1^3}{a_2^3 - a_1^3}}} \quad (6.88)$$

(where $L := \ln(-C_2/C_1)$) such that (note the independence of p) one has only the mentioned trivial solution $\mathcal{S} = 0 = Im W$. Thus there are no SUSY solutions.

Note that the conclusion would not change if one includes more generally a proper flux $E = e + e'\tau$ (not just to mimic formally $W^{(T)}$): one gets then for $\beta\tilde{C} := \beta C + E + W^{(T)}$ that $(\beta\tilde{C})_\tau = \beta_\tau C_E + \beta \frac{c/2}{a-3b}$ with $C_E = C + \frac{q}{d}e'$ leaving (6.74) intact.

6.3 The case III: $g + \frac{1}{3}h = 0$

For the flux components (again sticking to the case $c = 3d$)

$$(e_R^a | m_R^a) = (0, g, h | 0, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | 0, c, d) \quad (6.89)$$

one gets the flux superpotential $W_{flux} = gF_1 + hF_2 + Az_1 + Bz_2$ or

$$W_{flux} = g\left(-\frac{1}{2}Z^2 + \frac{3}{2}Z + \frac{17}{4}\right) + \frac{h}{3}\left(-\frac{1}{2}(Z^2 - z_2^2) + \frac{3}{2}(Z - z_2) + \frac{18}{4}\right) + \frac{A}{3}Z - pz_2$$

One gets as elimination equations $\frac{1}{3}D_{z_1}W = 0$ and $D_{z_2}W = 0$

$$g(-Z + \frac{3}{2}) + \frac{h}{3}(-Z + \frac{3}{2}) + \frac{A}{3} = \frac{3}{2i} \frac{Y^2}{Y^3 - y^3 + 9i\xi} W_{flux} \quad (6.90)$$

$$g(-Z + \frac{3}{2}) + \frac{h}{3}(-Z + z_2) + B = \frac{3}{2i} \frac{Y^2 - y^2}{Y^3 - y^3 + 9i\xi} W_{flux} \quad (6.91)$$

and the compatibility equation reads

$$\left[\frac{h}{3}\left(\frac{3}{2} - z_2\right) + p\right]Y^2 = \left[\left(g + \frac{h}{3}\right)\left(-Z + \frac{3}{2}\right) + \frac{A}{3}\right]y^2 \quad (6.92)$$

Now let us introduce again a linear binding between g and h . Whereas previously we had set $h = 0$ we put now $g + \frac{h}{3} = 0$. This gives

$$\left[\frac{h}{3}\left(\frac{3}{2} - z_2\right) + p\right]Y^2 = \frac{A}{3}y^2 \xrightarrow{y=Y^2/\beta} g\left(z_2 - \frac{3}{2}\right) + p = \frac{A}{3}\left(\frac{Y}{\beta}\right)^2 \quad (6.93)$$

(taking the imaginary part gives the indicated relation for y). One gets then for W_{flux}

$$W_{flux} = g\left(-\frac{1}{2}z_2^2 + \left(\frac{3}{2} - \frac{p}{g}\right)z_2 - \frac{1}{4}\right) + \frac{A}{3}Z \quad (6.94)$$

Equating with (6.90) gives

$$\frac{A}{3} \frac{2i}{3} \frac{Y^3 - \beta^{-3}Y^6 + 9i\xi}{Y^2} = g\left(\frac{1}{32} - \frac{3p}{2g} + \frac{p^2}{2g^2}\right) - \frac{1}{2g}\left[g\left(z_2 - \frac{3}{2}\right) + p\right]^2 + \frac{A}{3}Z \quad (6.95)$$

One gets thereby as effective 'superpotential'

$$W_{eff} = \frac{A}{3} \frac{2i}{3} \frac{Y^3 - \beta^{-3}Y^6 + 9i\xi}{Y^2} \quad (6.96)$$

where Y is determined by (gotten from taking $A_2\text{Re} - A_1\text{Im}$ of (6.95) to eliminate X)

$$\beta^{-3}Y^6 + 2Y^3 + CY^2 - 4 \cdot 9i\xi = 0 \quad (6.97)$$

One can not tune this to become a quadric in Y^3 as the demand for vanishing of

$$C = -\frac{27}{16} \frac{\beta}{A_1^2 + A_2^2} (g^2 - 48pg + 16p^2) \quad (6.98)$$

leads to the condition $g = 4(6 \pm \sqrt{35})p$, which can not be solved in integral fluxes.

However including again the fluxes $m_R^0 = -e$, $m_{NS}^0 = e'$ and the ensuing term $E = e + e'\tau$ in W_{flux} leads effectively to the following coefficient in the sextic

$$\tilde{C} = -\frac{27}{16} \frac{\beta}{A_1^2 + A_2^2} \left[(g^2 - 48pg + 16p^2) + \frac{32g}{A_2} (A_2 E_1 - A_1 E_2) \right] \quad (6.99)$$

$$= -\frac{27}{16} \frac{\beta}{A_1^2 + A_2^2} \left(g^2 - 48p \left[1 - \frac{2(e - \frac{a}{c}e')}{3p} \right] g + 16p^2 \right) \quad (6.100)$$

This is easily solved in special cases, such as $e - \frac{a}{c}e' = 2p$ giving $g = -4p$ leading to the sextic being just quadratic in Y^3 . However as the E -sector is used by us to include the $W^{(T)}$ -dependence formally, giving the $z_i(\tau, \mathcal{T}_i)$, any special tuning of it can not be kept under the further procedure, such that one will have still to face the more general sextic. When the E -sector is used for this purpose (to just mimic the $W^{(T)}$) one has to use just the expression (6.99). So one has now to work with the sextic with C replaced by $\tilde{C}$.

Now $\beta = \frac{d}{g}\tau_2$, gives $\beta_\tau = \frac{d}{2ig}$, $\beta_{\mathcal{T}_k} = 0$ and (6.99) gives $\tilde{C}_{\mathcal{T}_k} = i\frac{9}{2A}a_k W^k$ and a more complicated expression for $\tilde{C}_\tau$. From (6.97) with $C \rightarrow \tilde{C}$ one finds $Y_l(\beta^{-3}Y^4 + Y + \frac{\tilde{C}}{3}) = \frac{1}{2}(\beta^{-4}\beta_l Y^4 - \frac{\tilde{C}_l}{3})Y$ (here l is τ or $\mathcal{T}_i$). With the notation $\mathcal{B} := -\beta^{-3}Y^4 + 2Y + \frac{\tilde{C}}{3}$ one gets for the effective Kahler potential (up to additive constants) and superpotential

$$K_{eff}(\tau) = -\ln(Y^3 - y^3 + 9i\xi) = -2\ln Y - \ln \mathcal{B} \quad (6.101)$$

$$W_{eff}(\tau) = i\mathcal{A}\mathcal{B} \quad (\mathcal{A} := \frac{A}{6}) \quad (6.102)$$

One gets as effective G -function and SUSY conditions (note the marked difference in this case that now $A \in \mathbf{C}$ is τ -dependent whereas earlier $p \in \mathbf{R}$ was a constant)

$$G = -\ln(\tau - \bar{\tau}) - 2\ln Y - \ln \mathcal{B} + \ln |i\mathcal{A}\mathcal{B} + W^{(T)}|^2 + K(\mathcal{T}_k) \quad (6.103)$$

$$G_k = -2\frac{y_k}{y} + (2\Gamma - 1)\frac{\mathcal{B}_k}{\mathcal{B}} - a_k W^k \Gamma' + s_k = 0 \quad (6.104)$$

$$G_\tau = -2\frac{y_\tau}{y} + (2\Gamma - 1)\frac{\mathcal{B}_\tau}{\mathcal{B}} + i\frac{c}{6}\mathcal{B} \Gamma' + \frac{i}{2\tau_2} = 0 \quad (6.105)$$

where we use the abbreviations

$$\Gamma = \mathcal{B} \frac{\mathcal{A}_1(\text{Im } W^{(T)} + \mathcal{A}_1\mathcal{B}) - \mathcal{A}_2(\text{Re } W^{(T)} - \mathcal{A}_2\mathcal{B})}{|i\mathcal{A}\mathcal{B} + W^{(T)}|^2}, \Gamma' = \frac{-i(\text{Im } W^{(T)} + \mathcal{A}_1\mathcal{B}) + (\text{Re } W^{(T)} - \mathcal{A}_2\mathcal{B})}{|i\mathcal{A}\mathcal{B} + W^{(T)}|^2}$$

One can now start to proceed as in the previous examples. We will not write the ensuing equations here, as they become not especially illuminating. However, by now the general scheme should be rather clear. Proceeding in the manner described, the interested reader should be able to use this method to work out further cases. Note that each case will be of a somewhat different nature (cf. the remark here after (6.102)), and furthermore although for more general flux combinations the existence of SUSY vacua becomes more likely, on the other hand the explicit determination of W_{eff} also becomes more involved.

7 Discussion and Outlook

One of the most often studied scenarios of moduli stabilization is the KKLT set-up. This leads to supersymmetric AdS vacua with all moduli stabilized. Eventually this is uplifted to a SUSY-breaking dS vacuum. As the uplift process is not easily treated in a controlled framework other approaches to get moduli stabilization and dS vacua are of course of the highest interest [18], [19].

In this paper we stick just to the moduli stabilization aspect of the KKLT scenario. The common procedure employed in the KKLT framework is to use first [1] to fix the complex structure moduli z_i and the dilaton τ from a flux superpotential W_{flux} and then, afterwards, to use non-perturbative effects to stabilize the Kähler moduli $\mathcal{T}_k$. The underlying assumptions of the decoupling in this two-step procedure have been questioned [7] (cf. also [20]). This led to a procedure where only the z_i are integrated out what leads to an effective superpotential $W_{eff}(\tau)$ (in [7] conditions for a valid uplift were also considered). As this $W_{eff}(\tau)$ is a non-holomorphic quantity, as already pointed out in [8], the whole procedure actually has to be rephrased with the aid of the G -function of supergravity. When the integrating out-process is incorporated appropriately one actually gets not only a $W_{eff}(\tau)$ but a $W_{eff}(\tau, \mathcal{T}_k)$; it then contributes via the $\ln |W_{eff}(\tau, \mathcal{T}_k) + W^{(T)}(\mathcal{T}_k)|^2$ term in the effective G -function.

This program, which was described in [7] and [8] in a generic effective supergravity framework, is carried out here for one of the most intensely studied Calabi-Yau related models, the orientifold model of $\mathbf{P}_{11169}$ [18], which was also studied in the original KKLT framework [9]. Even more, this geometry was also the background to study further questions, such as inclusion of α'^3 -corrections [11], [12] or inflation [10].

The new approach is investigated here for this geometry in various flux combinations. More precisely, the determination of W_{eff} is illustrated mainly for the case

$$(e_R^a | m_R^a) = (0, g, 0 | 0, -a, -b) \quad , \quad (e_{NS}^a | m_{NS}^a) = (0, 0, 0 | 0, c, d) \quad (7.1)$$

One gets for $g \neq 0$ as effective superpotential (the case II above)

$$W_{eff}(\tau, \mathcal{T}_k) = i \frac{a - 3b}{3} \left(\frac{d}{g} \tau_2 \frac{a + c\tau_1 + \frac{9}{2}g + \frac{3g}{d\tau_2} \text{Im} W^{(T)}(\mathcal{T}_i)}{a - 3b} - y \right) \quad (7.2)$$

Here y is given as function of τ and $\mathcal{T}_k$ by the Cardano formula for the cubic

$$0 = y^3 - \left[3 \frac{d}{g} \tau_2 \frac{a + c\tau_1 + \frac{9}{2}g + \frac{3g}{d\tau_2} \text{Im} W^{(T)}(\mathcal{T}_i)}{a - 3b} \right] y^2 + 2 \left(\left(\frac{d}{g} \tau_2 \right)^3 + 9i\xi \right) \quad (7.3)$$

Here $W^{(T)}$ denotes $\sum_{k=1}^2 C_k e^{-a_k \mathcal{T}_k}$.

Above we did assume that $g \neq 0$. In the case $g = 0$ one gets (case I above)

$$W_{eff}(\tau, \mathcal{T}_k) = i(d\tau + \frac{a}{3}) \left(Y + 3 \frac{(a + c\tau_1)\text{Im } W^{(\mathcal{T})} - c\tau_2\text{Re } W^{(\mathcal{T})}}{|a + c\tau|^2} \right) \quad (7.4)$$

Again, here Y is given as function of τ and $\mathcal{T}_k$ by the Cardano formula for the cubic

$$0 = Y^3 + 9 \left[\frac{(a + c\tau_1)\text{Im } W^{(\mathcal{T})} - c\tau_2\text{Re } W^{(\mathcal{T})}}{|a + c\tau|^2} \right] Y^2 - 18i\xi \quad (7.5)$$

In these cases one can resolve analytically the remaining supersymmetry conditions on τ and the $\mathcal{T}_k$. As the case $g = 0$ is somewhat degenerate ($N_{flux} = 0$) we give the treatment fully only for our main case $g \neq 0$. There one finds that no supersymmetric solutions to the ensuing supersymmetry conditions for τ and the $\mathcal{T}_k$ exist.

There is a third, more complicated case with a non-zero e_R^2 turned on (the case III above), where we also give the effective superpotential and pave the way for the treatment of the supersymmetry conditions. As in the present paper our aim was just to elucidate the concrete improved KKLT procedure in the spirit of [7] and [8], we are content here to illustrate this new set-up with a number of non-trivial examples where actually all the steps can be carried out in closed analytical form (this program is surely completely worked out at least for the main case $g \neq 0$, i.e. case II).

The worked out examples should make it sufficiently clear how the preceding considerations could be generalised further. One next step would be to 'solve' the $\mathbf{P}_{11169}$ [18] model in the sense of allowing (more) general flux combinations. It would be especially interesting to turn on the flux e_R^0 which leads to a contribution $e_R^0 F_0$ in W_{flux} which would be even of cubic degree in the z_i and so will lead to a more complicated dependence in W_{eff} . As the treatment [9] along the lines of the original KKLT set-up contains this flux this would open up the possibility for a direct comparison. Of course alternatively one can study the KKLT procedure also in one of the simpler examples by demanding $D_\tau W_{flux} = 0$ in addition to $D_{z_i} W_{flux} = 0$. We indicated this in (6.13) and a similar analysis is easily given for $g \neq 0$. Another interesting avenue to explore would be to combine the appropriate modification of the KKLT procedure outlined here with further questions such as the inclusion of α'^3 -corrections [11], [12] or inflation [10]. Furthermore one could carry out the program described here for other examples of low parameter Calabi-Yau (orientifold) models. Finally one could, following [7], work out the appropriate criterion for a successful uplift to dS space in connection with the question of stability, i.e. one could study the nature of the supersymmetric points with respect to the stronger dS stability criterion. Touching thereby the realm of non-supersymmetric solutions one could study numerically their existence already for the potential arising here (without uplift).

We would like to thank S. Theisen for participation at some stages of this work.

A SUSY conditions in case I

Let us consider the real and imaginary parts of $G_k = 0$ and $G_\tau = 0$ (with $W := W^{(T)}$)

$$-2\frac{\text{Re } Y_k}{Y} + (2\Gamma - 1)\frac{\text{Re } \mathcal{B}_k}{\mathcal{B}} - a_k \frac{\text{Re} [W^k(-i\bar{\mathcal{A}}\mathcal{B} + \bar{W})]}{|i\mathcal{A}\mathcal{B} + W|^2} = -s_k \quad (\text{A.6})$$

$$-2\frac{\text{Im } Y_k}{Y} + (2\Gamma - 1)\frac{\text{Im } \mathcal{B}_k}{\mathcal{B}} - a_k \frac{\text{Im} [W^k(-i\bar{\mathcal{A}}\mathcal{B} + \bar{W})]}{|i\mathcal{A}\mathcal{B} + W|^2} = 0 \quad (\text{A.7})$$

$$-2\frac{\text{Re } Y_\tau}{Y} + (2\Gamma - 1)\frac{\text{Re } \mathcal{B}_\tau}{\mathcal{B}} + \frac{c}{3}\mathcal{B} \frac{\mathcal{A}_1\mathcal{B} + \text{Im } W}{(\mathcal{A}_1\mathcal{B} + \text{Im } W)^2 + (-\mathcal{A}_2\mathcal{B} + \text{Re } W)^2} = 0 \quad (\text{A.8})$$

$$-2\frac{\text{Im } Y_\tau}{Y} + (2\Gamma - 1)\frac{\text{Im } \mathcal{B}_\tau}{\mathcal{B}} + \frac{c}{3}\mathcal{B} \frac{-\mathcal{A}_2\mathcal{B} + \text{Re } W}{(\mathcal{A}_1\mathcal{B} + \text{Im } W)^2 + (-\mathcal{A}_2\mathcal{B} + \text{Re } W)^2} = -\frac{1}{2\tau_2} \quad (\text{A.9})$$

Note first that the middle two real equations $\text{Im } G_k = 0$ and $\text{Re } G_\tau = 0$, which have a zero on the right hand side, have a major part in common (again W denotes $W^{(T)}$)

$$\text{Im } \tilde{C}_k \left[\frac{2}{Y + 2\tilde{C}} + (2\Gamma - 1)\frac{2\tilde{C}}{Y + 2\tilde{C}} \frac{1}{Y + \tilde{C}} \right] = a_k \frac{\text{Im}(W^k(-i\bar{\mathcal{A}}\mathcal{B} + \bar{W}))}{|i\mathcal{A}\mathcal{B} + W|^2} \quad (\text{A.10})$$

$$\text{Re } \tilde{C}_\tau \left[\frac{2}{Y + 2\tilde{C}} + (2\Gamma - 1)\frac{2\tilde{C}}{Y + 2\tilde{C}} \frac{1}{Y + \tilde{C}} \right] = -\frac{c}{3}\mathcal{B} \frac{\mathcal{A}_1\mathcal{B} + \text{Im } W}{|i\mathcal{A}\mathcal{B} + W|^2} \quad (\text{A.11})$$

Using (A.11) in (A.10) gives

$$-\frac{c}{3}\mathcal{B} \frac{\text{Im } \tilde{C}_k}{\text{Re } \tilde{C}_\tau} (\mathcal{A}_1\mathcal{B} + \text{Im } W) = a_k \left(-\text{Re } W^k(\mathcal{A}_1\mathcal{B} + \text{Im } W) + \text{Im } W^k(-\mathcal{A}_2\mathcal{B} + \text{Re } W) \right) \quad (\text{A.12})$$

Dividing by a_k and summing over k one arrives at

$$\frac{-c\mathcal{B}}{\text{Re } \tilde{C}_\tau} \frac{\mathcal{A}_1\text{Re } W + \mathcal{A}_2\text{Im } W}{2A\bar{A}} (\mathcal{A}_1\mathcal{B} + \text{Im } W) = -\mathcal{B}(\mathcal{A}_1\text{Re } W + \mathcal{A}_2\text{Im } W) \quad (\text{A.13})$$

This implies $\mathcal{A}_1\text{Re } W + \mathcal{A}_2\text{Im } W = 0$ for otherwise one would get $\mathcal{B} = 2\frac{\mathcal{A}_2\text{Re } W - \mathcal{A}_1\text{Im } W}{\mathcal{A}_1^2 + \mathcal{A}_2^2}$ from

$$(\mathcal{A}_1\mathcal{B} + \text{Im } W)(\mathcal{A}_1^2 + \mathcal{A}_2^2) = 2\mathcal{A}_1\mathcal{A}_2\text{Re } W - (\mathcal{A}_1^2 - \mathcal{A}_2^2)\text{Im } W \quad (\text{A.14})$$

But one has that $\mathcal{B} = Y - \frac{\mathcal{A}_2\text{Re } W - \mathcal{A}_1\text{Im } W}{\mathcal{A}_1^2 + \mathcal{A}_2^2}$; this would then give $Y = 3\frac{\mathcal{A}_2\text{Re } W - \mathcal{A}_1\text{Im } W}{\mathcal{A}_1^2 + \mathcal{A}_2^2} = -3\tilde{C}$ which is excluded from (6.15) as $\xi \neq 0$. So the remaining possibility is $\text{Im } W = -\frac{\mathcal{A}_1}{\mathcal{A}_2}\text{Re } W$ and so $\tilde{C} = -\frac{\text{Re } W}{\mathcal{A}_2}$. Applying now (A.11) in (A.9) would give finally $0 = -\frac{1}{2\tau_2} \frac{3}{c\mathcal{B}} \frac{\mathcal{A}_1^2 + \mathcal{A}_2^2}{\mathcal{A}_2} (\mathcal{A}_2\mathcal{B} + \text{Re } W) \frac{\mathcal{A}_1}{\mathcal{A}_2} \text{Re } W$, so $\mathcal{A}_1 = 0$ or $\text{Re } W = 0$ (and so in any case $\text{Im } W = 0$); however above we had assumed that $\text{Re } \tilde{C}_\tau \neq 0$ and so this can not be argued.

Rather one has from $\text{Im } W = -\frac{\mathcal{A}_1}{\mathcal{A}_2}\text{Re } W$ and $\tilde{C} = -\frac{\text{Re } W}{\mathcal{A}_2}$ (still assuming $\text{Re } \tilde{C}_\tau \neq 0$) that (A.9) gives finally $4\mathcal{A}_2^2\mathcal{B}(\text{Re } W)^2 = (\mathcal{B} + 2\mathcal{A}_2\text{Re } W)((\mathcal{A}_2\mathcal{B})^2 - (\text{Re } W)^2)$ or

$$Y^3 + (3\tilde{C} - 2\mathcal{A}_2^2\tilde{C})Y^2 + 2(1 - 4\mathcal{A}_2^2)\tilde{C}^2Y + 4\mathcal{A}_2^2 \cdot \tilde{C}^3 = 0 \quad (\text{A.15})$$

Combining with (6.15) one gets eliminations with which $G_k = 0$ can be treated further.
